INTRODUCTION

- We employed a simple one-parameter model to model active regions with multi-polar configurations.
- LFFF model is assumed as it provides the single parameter alpha.
- Pseudo-coronal loop images are formed from the multi-polar configurations.
- Alpha value determined by CNN classification and regression.
- Method extended to include active region AR11117.
- Response of pseudo-coronal loop images to that of real coronal loop images observed.

LINEAR FORCE-FREE FIELD

- Certain assumptions need to be made about the nature of the magnetic field in order to model a solar coronal magnetic field, **B**.
- In the region between the photosphere and the upper corona, the plasma forces are dominated by the magnetic field.
- Based on this observation, all lower order non-magnetic forces can be neglected to the first order. This model leads to the force-free approximation.
- A force-free magnetic field gives the simplest model for the corona, which is non-potential. It occurs when the electric current density vector is parallel to the magnetic field which causes the Lorentz forces to disappear. The linear force free fields are characterized by

a. Multi-polar configurations and vector magnetogram of AR11117

b. Pseudo-coronal loops for AR11117

 $abla \cdot \mathbf{B} = \mathbf{0},$

and

 $(\nabla \times \mathbf{B}) = \alpha \mathbf{B}.$

(2)

(1)

• The case where α = constant is called a linear force-free field (LFFF).

CNN RESULTS

CNN - Alpha Response on EUV Data

- In the process of validating our pseudo-coronal loop renderings we observed a change in the class of alpha when tested against EUV images of the same active region.
- This alpha change corresponds with flare events and provides a global nonpotential value using EUV data.

Visualizing the CNN layers showing the various features learned in convolutional filters

• The tables below show the classification accuracy for the CNN models used along with the results from transfer learning applied.

• We observed this on two active regions, AR11117 and AR11283.

b. GOES X-Ray Flux for AR12283 on September 6, 2011

 Based on these results we are looking at SHARP parameters and their response during flaring events.

• When used with regression to predict the Alpha values we obtained an MAPE of 4% - 9%.

• We are also looking at predicting these parameters from AIA EUV data.

CONCLUSION

We demonstrated the effectiveness of determining the alpha parameter from the CNN training of pseudocoronal loops. The method also indicates a correlation between change in alpha value and EUV data during flare events. We are further exploring this correlation and its effect on space weather.
