The University of Alabama in Huntsville ECE Department CPE 526 01 Final Exam April 23, 2020

		Name:
1.	(5 points) Draw the transist	tor-level diagram of a three input CMOS NAND gate.
2.	the cost of individual parts	For FPGA and CBIC circuits are \$50,000 and \$800,000, respectively, and s for FPGA and CBIC circuits are \$52 and \$11, respectively, what is the volume for these two types of circuits?
	_	
3.	(1 point) A	provides stimuli and captures responses.
4	(1 point) A	is a set of relational expressions that must be true for the chosen
	value of the variables.	
5.	(1 point)	are pieces of declarative code that check the relationships

between design signals, either once or over a period of time.

6. (6 points) For the process given below, A, B, C, and D are all integers that have a value of 0 at time = 10 ns. If E changes from '0' to '1' at time 20 ns, specify all resulting changes. Indicate the time at which each change will occur, the signal/variable affected, and the value to which it will change.

```
process
   variable F : integer := 1; variable A : integer := 0;
begin
   wait on E;
   A := 1;
   F := A + 5;
   B <= E + 3 after 4 ns;
   A := A + 5;
   C <= F + 2;
   D <= A + 5 after 12 ns;</pre>
```

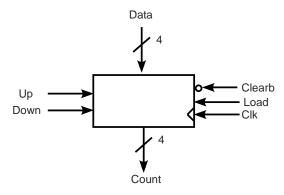

end process;

Scheduling Rules	Transport	Inertial	
New before existing	Overwrite existing Overwrite existing		
New after existing	Append new	If $v_{new} = v_{existing}$, append new	
		Elsif t _{new} -t _{existing} > reject append new	
		Else overwrite existing	

Time	Α	В	С	D	Е	F
10 ns	0	0	0	0	0	1
20 ns	1	0	0	0	1	1

7.	(1 point)	(True/False) Gate delay is the dominant factor in determining the delay of a
	path.	
8.	(1 point)	_ (True/False) Design verification is a trivial task.
9.	(1 point)	are primitives that are all the same height and varying widths.
10.	(1 point) A	is used in VHDL to bind an architecture to an
	instantiation of an	entity.

11. (8 points) Create a System Verilog interface for a 4 bit counter that has an asynchronous clear input that is active low. It also has active high LOAD, UP and DOWN inputs. When data is loaded into the counter, counting proceeds from that loaded value. Include as part of the interface a clocking block that uses a rising edge clocking scheme. Also include modports from a testbench and from a DUT perspective.

12. (4 points) List the four types of paths that must be considered when determining the maximum frequency of a circuit.

13. (13 points) a. (2 points) VHDL entity, b. (11 points) VHDL architecture Design a finite state machine for control of lights used to start a race, which works as follows.

Inputs: Reset, Start, Clock Outputs: Red, Yellow, Green

- Only one light can be on at any time.
- The Reset signal forces the circuit into a state in which the red light is turned on.
- When the Start signal is activated, the red light stays on for at least one second, then the yellow light is turned on.
- The yellow light stays turned on one second and then the green light is turned on.
- The green light stays on for at least three seconds and then the red light is turned on and the circuit returns to its reset state.
- The input clock has a period of 1 sec.

14. (15 points) Create a VHDL architecture for a 3-to-8 decoder with an active-low enable input which uses a case statement to represent the functionality of the decoder. Create an entity and its accompanying architecture that represents a 4-to-16 decoder by using two instances of the en_dec_328 entity. a. (6 points) 3-to-8 decoder architecture, b. (3 points) 4-to-8 decoder entity, c. (6 points) 4-to-8 decoder architecture

```
entity en_dec_328 is
  port (a : in std_logic_vector (2 downto 0);
        en : std_logic;
        d : out std_logic_vector (7 downto 0));
end entity en_dec_328;
```

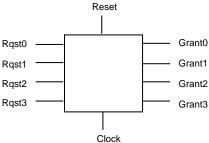

- (1 point) ______ (True/False) Multiple assignments to a signal within a process can cause that signal to have multiple drivers.
 (1 point). _____ (True/False) If you give a SystemVerilog simulator the same seed and the same testbench, it always produces the same results.
 (1 point) _____ (True/False) Assertions in System Verilog use negative logic.
- 18. (8 points An ARM Advanced High-performance Bus (AHB) has the following signals.

Signal	Width	Direction	Description
HCLK	1	Output	Clock
HADDR	21	Output	Address
HWRITE	1	Output	Write flag: 1=write, 0=read
HTRANS	2	Output	Transaction type: 2'b00=IDLE, 2'b10=NONSEQ
HWDATA	8	Output	Write data
HRDATA	8	Input	Read data

Create a class to encapsulate the AHB transactions. In this class constrain:

- a. The address (HADDR) to be in the lower 5 addresses and upper 5 addresses each with probability 40% and the other addresses with probability 20%.
- b. HTRANS to NONSEQ (HTRANS = 2'b10) and IDLE (HTRANS = 2'b00)...
- c. All other AHB signals are randomized but unconstrained.

19. (13 points) An arbiter is a circuit that allows at most one subsystem at a time to use a shared resource. A four-way arbiter is shown below. Each subsystem sets its request signal to 1 when it wants to use the resource. When the arbiter sets the grant signal to 1, the subsystem uses the resource. The subsystem sets its request back to 0 when it has finished, and waits for grant to be 0 before starting a subsequent request. While a subsystem is granted use of the resource, other requests must wait, rather than pre-empting the active subsystem. Subsystems are granted requests in order, starting with 0, then 1, 2, 3 and back to 0. A subsystem is skipped if it has no pending request.

As part of creating a SystemVerilog testbench for this device, an interface and a packet for randomization has been created. The requests are being driven by the request device modeled in VHDL below. Each req_dev has an associated test program. The test program is responsible for issuing a signal to the req_dev to reset it and providing a time parameter. After reset, the requesting device raises its request line high and keeps it high for the amount of time provided by the test program. Since req_dev works on the positive edge of the clock, the test program will provide inputs to it on the negative edge of the clock. Complete the test0 program so that it repeats the following process 100 times.

- 1) waits a random number of clock cycles to set the reset for reqdev to 1.
- 2) then provides a random number of cycles that regdev will hold a request high.
- 3) sets the reset to 0 after one clock cycle
- 4) waits one more cycle
- 5) waits for req dev to lower request to 0
- 6) waits one more clock cycle

```
interface arbiter if (input bit clk);
 logic [3:0] REQUEST, GRANT, GEN REQ;
 logic RESET;
  int REQ TIME3, REQ_TIME2, REQ_TIME1, REQ_TIME0;
endinterface
module top;
 bit clk;
 always #5ns clk = \simclk;
 arbiter if arbiterif(clk);
 arbiter u1 (.CLK (clk), .REQ (arbiterif.REQUEST),
              .GRANT (arbiterif.GRANT), RESET (arbiterif.RESET));
 req_dev u2 (.GEN_REQ (arbiterif.GEN_REQ[3]), .REQ_TIME (arbiterif.REQ_TIME3),
              .REQUEST (arbiterif.REQUEST[3]), .GRANT (arbiterif.GRANT[3]),
              .RESET (arbiterif.RESET),.CLK (clk));
 req dev u3 (.GEN REQ (arbiterif.GEN REQ[2]), .REQ TIME (arbiterif.REQ TIME2),
              .REQUEST (arbiterif.REQUEST[2]), .GRANT (arbiterif.GRANT[2]),
              .RESET (arbiterif.RESET), .CLK (clk));
 req_dev u4 (.GEN_REQ (arbiterif.GEN_REQ[1]), .REQ_TIME (arbiterif.REQ_TIME1),
              .REQUEST (arbiterif.REQUEST[1]), .GRANT (arbiterif.GRANT[1]),
              .RESET (arbiterif.RESET),.CLK (clk));
  req dev u5 (.GEN REQ (arbiterif.GEN REQ[0]), .REQ TIME (arbiterif.REQ TIME0),
```

```
.REQUEST (arbiterif.REQUEST[0]), .GRANT (arbiterif.GRANT[0]),
              .RESET (arbiterif.RESET), .CLK (clk));
  test3 t1(arbiterif);
  test2 t2(arbiterif);
  test1 t3(arbiterif);
  test0 t4(arbiterif);
  testr t5(arbiterif);
endmodule : top
package mine;
  class Packet_g;
    // The ran\overline{d}om variables
    rand int generate t, request t;
    // Limit the values
    constraint c1 {generate_t < 300; generate_t > 100;
                  request_t < 101; request_t > 0;}
  endclass : Packet_g
endpackage : mine
entity REQ DEV is
  port(GEN_REQ : in std_logic;
       REQ_TIME : in integer range 0 to 100;
       REQUEST : out std_logic;
       GRANT : in std_logic;
RESET, CLK : in std_logic);
end REQ DEV;
import mine::*;
module test0(arbiter_if arbif);
```

endmodule : test0

20. (6 points) Given the following constraints, what are the solution probabilities?

```
Class MemTrans;
  Rand bit x;
  Rand bit [1:0] y;
  Constraint c_xy
  {
     y inside {[x:3]};
     solve x before y;
  }
Endclass
```

Solution	Х	V	Probability
301011011	Χ	у	Probability
Α	0	0	
В	0	1	
С	0	2	
D	0	3	
E	1	0	
F	1	1	
G	1	2	
Н	1	3	

- 21. (8 points) For the class below, write two covergroups to collect coverage on the test plan requirements
 - 1. "All ALU opcodes must be tested". Assume that the opcodes are valid on the positive edge of signal clk.
 - 2. "operand1 shall take on the values maximum negative (-128), zero, and maximum positive (127)". Define a coverage bin for each of these values as well as a default bin.

```
typedef enum {ADD, SUM, MULT, DIV} opcode_e;
class Transaction;
  rand opcode_e opcode;
  rand byte operand1;
  rand byte operand2;
endclass : Transaction
Transaction tr;
```
